Abstract

Smart-microgrid is a potential solutions being studied for future distributed generation systems. Due to the distributed topology of the emerging Smart Grid (SG) systems, the paradigm of Multi-Agent Systems (MAS) has been showing an useful tool that has been addressed in different applications. In this paper, the major issues and challenges in MAS and smart-microgrids are discussed, and a review of state-of-the-art applications and trends is presented.

1. Introduction

Smart grid is considered as a future of power grid which is able to manage the production, transmission and distribution of electricity by using information technology, distributed systems and artificial intelligence. SG has become a major challenge for developed and developing nations in both research and utilization aspects [1, 2]. It is expected to play an important role order to resolve many issues of current power grid systems [1]. The latter will be now composed of a mesh of networked MG collaborating to deliver electricity to consumers [3].

Future MG may equip customers with distributed generation and storage systems that can change their overall demand behavior. Rogers, Ramchurn & Jennings [4] highlighted that demand side, the consumers, will have to adapt to the available resources, in contrast to the current model in which the supply should always match the demand. Providing autonomous assistance in order to assist complex decision making tasks will be required by an increasing number of MG users.

The need of reducing environmental impacts, as emissions of greenhouse gases, motivate the growth of Renewable Energy Resources (RER) based systems [5, 6, 7]. The potential for RER is growing quick and it is expected that it will exponentially exceed the world's energy demand [8]. SG's infrastructure should also provides new opportunities for the grid and its customers for information exchange regarding real-time electricity rates and demand profiles. [9]. Energy management system of SG is tightly associated with the communications between stakeholders and entities. Providing essential infrastructure for consumers and stakeholders to monitor and control their energy production and usage should be taken into account over the new systems.

Coordination and controlling of all these new emerging components remains a great challenge. Advanced networking, as well as information and communication technologies (ICTs), have been motivating the integration of the conventional power grid in smarter ways [10], known as a peer-to-peer or distributed multi-agent system (MAS). Autonomous control of SG system allows placing additional DGs without reengineering the system, and using it in the peer-to-peer model eliminates the requirement of a complex central controller and associated telecommunication facilities [11]. MAS is one of the most fastest growing domains in agent oriented technology which deals with modeling of autonomous decision making entities [12], which have been showing to be crucial in SG operations.

The need to integrate both field of knowledge, MAS and SG, have increased extensively in recent years around the world. Figure 1 shows the number of publications relating MAS and SG in the Scopus database, performed in 9th, April, 2015.

In particular, the MAS paradigm can be adapted to model, control, manage or test the operations and management of MG . MG had become a basic and

Figure 1

42 fundamental infrastructure in the SG environment and have been receiving at-
 43 tention in recent literature works [13, 14]. Microgrid is been intensively studied
 44 as a possible future energy system paradigm and its control. As noticed by
 45 Jiayi, Chuanwen & Rong [15], MAS technology can be applied in it in order
 46 to solve number of specific operational problems, such as: “First of all, small
 47 Distributed Energy Resources (DER) units have different owners, and several
 48 decisions should be taken locally so centralized control is difficult. Furthermore
 49 MGs operate in a liberalized market; therefore the decisions of the controller of
 50 each unit concerning the market should have a certain degree of ”intelligence“.
 51 Finally the local DER units besides selling power to the network have also
 52 other task: producing heat for local installations, keeping the voltage locally
 53 at a certain level or providing a backup system for local critical loads in case
 54 of a failure of the main system” MG systems aggregates many DER and loads
 55 together as an autonomous entity [16]. Its use in microgrid has been tackled by
 56 different researches and still a complex task [12]. Figure 2 shows the number of
 57 publications relating MAS and MG.

Figure 2

58 The interesting in developing applications involving MAS paradigm is also

59 founded by private sectors, where some patents have been registered in the last
60 years. A patent consisted in a method configured for execution in a computing
61 device in a microgrid, the computing device assigned to a particular power
62 source in the microgrid was registered by [17]. Another one, by...

63 Different distributed management solutions based on the paradigm of MAS
64 applied to smart-microgrid are analyzed in this survey. Section 2 describes
65 different applications involving MAS and coordination, control and security of
66 different SG components. Section 2.1 described the its use on DER and Section
67 2.2 indicates its use in order to promote SG security. Section 2 presents MAS
68 applications done in field of MG, energy storage systems are discussed in section
69 3.1, demand control system are presented in Section 3.2. Section 4 introduces
70 some future applications expected in the field of Smart-Microgrids. Finally,
71 some conclusions are drawn in Section 5.

72 2. MAS and SG control

73
74
75

76 A multi-agent based protection framework is proposed to enhance the sta-
77 bility of smart grids in Rahman, Mahmud, Pota & Hossain [18]. In Rosa, Silva
78 & Miranda [19], a MAS technology-based platform was evaluated to be applied
79 as potential applications in management and simulation processes in power sys-
80 tems .

81 2.1. DER

82 Studies in the field of DER management usually request the inclusion of
83 criterion like fault tolerance or adaptability. Lagorse, Paire & Miraoui [20]
84 reported that these systems are often difficult to design because of the “top-
85 down” approach used: the designer generally knows how each component has
86 to respond separately. Centralized management system focuses its attention
87 solely on the overall reaction of the system. Thus, the use of paradigm based
88 on MAS have been showing to be reasonable [21]. Other approaches focused
89 on energy management issue of a Distributed Generation System (DGS) for
90 ensuring energy supply with high security, as recently done by Dou & Liu [22].

91 Bousquet & Le Page [23] presented a review of MAS and RER applications
92 to ecosystem management. Purnomo, Mendoza, Prabhu & Yasmi [24] developed
93 and analysed a multi-agent simulation model of a community managed forest.

94 Zhao, Xue, Zhang, Wang & Zhao proposed a MAS system for implementing
95 a PV-small hydro hybrid microgrid (MG) at high altitude, DER in the smart-
96 microgrid were controlled via an energy management system (EMS) in order to
97 improve system operation stability.

98 2.2. Security

99
100

101 3. MAS and Smart-Microgrid

102

103 A MG composed of a train station, wind power plant and district was inves-
104 tigated in Kuznetsova, Li, Ruiz & Zio [25]. An optimization tool was applied to
105 solve goal-directed actions planning of each agent, based on robust optimization
106 concepts. Their framework showed to be able to improve system reliability and
107 decreases power imbalances.

108 Dimeas & Hatziargyriou [26] propose optimization of the use of local dis-
109 tributed resources, feeding of local loads and improving operation simplicity.
110 They proposed four kinds of agents: production agent, consumption agent,
111 power system agent and a coordinating agent. “In general, agents represent in-
112 dividual entities in the network. Each participant is modeled as an autonomous
113 participant with independent strategies and responses to outcomes. They are
114 able to operate autonomously and interact pro-actively with their environment.
115 Such characteristics of agents are best employed in situation like MicroGrid
116 modeling.”

117 3.1. Energy storage

118 Energy storage have been widely analyzed for MG systems. Its use has im-
119 portant benefits, improving dynamic stability, transient stability, voltage sup-
120 port and frequency regulation [27]. Furthermore, they can also be used for
121 minimizing global cost and environment impact. Current smart-microgrid sce-
122 narios may include different renewable energy resources and different storage
123 units. A wide range of applications exist for Energy Storage Systems (ESS) any
124 may now takes profit of MAS [20] Power dispatching problems including ESS
125 [28, 29] deals with communications of several different SG components, such as
126 energy storage devices, DER and forecasting agents. It is expected that it will
127 receive efforts from MAS application and, specially, when handling with PEVs
128 as a possible storage unit [30].

129 The field of PEV have been also requesting aids from MAS, since connect-
130 ing it to DER recharging its batteries without any control may overload the
131 transformers and cables during peak hours [31].

132 3.2. Demand control

133

134

135 4. Future MAS in the context of Smart-Microgrid
